(57) Abstract :
Gingival biotype is the thickness of the gingiva in the facio-palatal dimension. It has a significant impact on the outcome of the restorative, regenerative and implant therapy. Various invasive and non-invasive methods were proposed to measure tissue thickness. These include direct measurement, probe transparency (TRAN) method, ultrasonic devices, and cone-beam computed tomography (CBCT) scan. The present disclosure relates to a dental science and in particular to a method for detection of gingival phenotype for dental implant treatment planning. Sensor and image capturing module is attached to William's graduated probe which is then inserted horizontally transgingivally. The captured image and sensor data is then transferred to controller where a memory unit has a prestored data and values to measure thickness of soft tissue. further data analyzing module is activated. output module shows result as obtained at end of process which displays values of thickness of gingiva in millimeter.

Method [10]

A successful denture may be defined as one in which the three cardinal factors of mechanics, esthetics, & phonetics are so completely & perfectly harmonized, that the patient can not only chew his food properly, but also experiences equal satisfaction from the contribution of the denture to his facial expressions & speech. It is frequently found that even with mechanically satisfactory denture the patient will complain of not being able to chew well. Perhaps, with only a slight improvement in esthetics, the patient will no longer complain of the inefficiency of dentures. The goal of a successful denture today is to attain a healthy beauty by harmonizing morphology & function.

Esthetics in Complete Denture

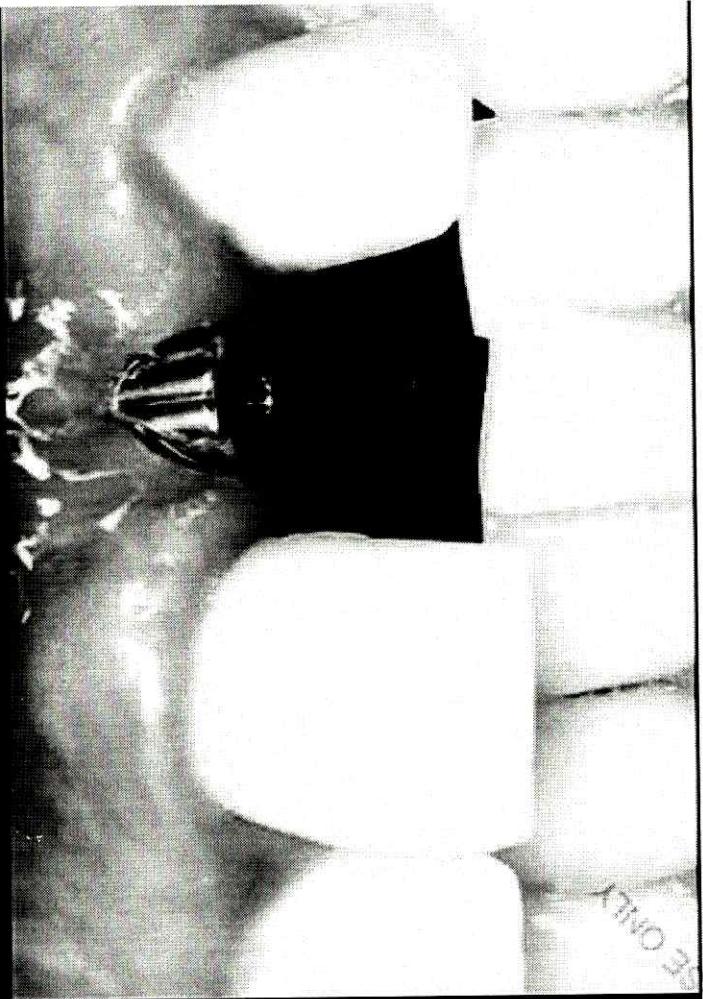

Dr. Nikita Kale
Vivekanand Jadhav
Babita Yeshwante

I am a postgraduate student passionate about esthetics in all aspects of dentistry especially natural dentures, mimicking nature is the prime goal of my life.

Implant impression is a crucial step for success of implant prosthesis. Selection of materials, type of impression technique(open tray or closed tray) everything is illustrated with diagrams in the above book. The wide applicability and ever increasing pace of the implantology research has resulted in the evolution of various implant impression techniques available for the dentist have improved in terms of the ability of various impression materials. Because of this, the selection of appropriate impression technique that suits the patients condition and dentists' operation skill has become more challenging. Hence it is vital to have a knowledge on the various techniques in order to create a successful implant supported prosthesis.

The aim of this systematic review was to evaluate proper site for orthodontic mini-implant placement and Does bone density vary in anterior and posterior region or buccal and palatal region in maxilla and mandible. In this systematic review, 15 *In vivo* studies and 2 *In vitro* studies were included. Data from a total of 1277 patient's radiograph were included in this review, out of which 821 are CBCT scan and 456 are CT scan. The density and site suitable for the orthodontic mini-implant placement is examined. In conclusion, males have a thicker and higher density alveolar cortical bone than females. Adults show a thicker alveolar cortical bone than adolescents. In the mandible, the alveolar cortical bone is more compact and thicker than in the maxilla. High value of thickness and density characterize posterior regions of both jaws. Palatal bone is thicker than the buccal cortical bone. There is a significant linear increasing of thickness and density from crest to base of alveolar crest.

Features of Orthodontic Mini-Implant

Their Effect on Primary Stability

978-620-4-98694-4

The growing demand for orthodontic treatment methods that require minimal compliance and provide particularly for adults, has led to the expansion of implant technology in orthodontics i.e. Temporary (TAD). Temporary anchorage devices (TAD) are proving as an excellent alternative to traditional orthodontics have been increasingly used in the field of Orthodontics for skeletal anchorage. Various implant designs available in the market to perform different functions at different sites in the oral cavity. Long-term mini-implants are designed to provide both primary and secondary stability, two closely related phenomena. Immediately after the mini-implant retention is entirely mechanical, due primarily to the characteristics and amount of the bone-contact in the cortical bone. This mechanical type of retention is called primary stability. For orthodontists, primary stability allows mini-implants to be immediately loaded.
